### 1.5 Template

```
#include <bits/stdc++.h>
using namespace std;

#define _ ios::sync_with_stdio(0);cin.tie(0);
#define endl '\n' // CAREFUL INTERACTIVE
```

```
typedef long long ll;
const int INF = 0x3f3f3f3f3f;
const ll LINF = 0x3f3f3f3f3f3f3f3f3f1l;
int main() { _
    cout << fixed << setprecision(0); // remove when working
        with float
    return 0;
}</pre>
```

# 2 Dynamic Programming

### 2.1 Fractional Knapsack

```
/*
Given two arrays, val[] and wt[], representing the values
     and weights of items, and an integer capacity
     representing the maximum weight a knapsack can hold,
     the task is to determine the maximum total value that
     can be achieved by putting items in the knapsack. You
     are allowed to break items into fractions if necessary.
Note: Return the maximum value as a double, rounded to 6
     decimal places.
Input: val[] = [60, 100, 120], wt[] = [10, 20, 30], capacity
Output: 240
Explanation: By taking items of weight 10 and 20 kg and 2/3
     fraction of 30 kg.
Hence total price will be 60+100+(2/3)(120) = 240
Input: val[] = [500], wt[] = [30], capacity = 10
Output: 166.667
// C++ code to implement Fractional Knapsack Problem
#include <bits/stdc++.h>
using namespace std:
// Comparison function to sort items based on value/weight
bool compare(vector<int>& a, vector<int>& b) {
```

```
double a1 = (1.0 * a[0]) / a[1]:
   double b1 = (1.0 * b[0]) / b[1]:
   return a1 > b1:
double fractionalKnapsack(vector<int>& val. vector<int>& wt.
     int capacity) {
   int n = val.size();
   // Create 2D vector to store value and weight
   // items[i][0] = value. items[i][1] = weight
   vector<vector<int>> items(n, vector<int>(2));
   for (int i = 0: i < n: i++) {</pre>
       items[i][0] = val[i]:
       items[i][1] = wt[i];
   // Sort items based on value-to-weight ratio in
        descending order
   sort(items.begin(), items.end(), compare);
   double res = 0.0;
   int currentCapacity = capacity;
   // Process items in sorted order
   for (int i = 0: i < n: i++) {</pre>
       // If we can take the entire item
       if (items[i][1] <= currentCapacity) {</pre>
           res += items[i][0]:
           currentCapacity -= items[i][1];
       }
       // Otherwise take a fraction of the item
           res += (1.0 * items[i][0] / items[i][1]) *
                currentCapacity;
           // Knapsack is full
           break:
   return res;
int main() {
   vector<int> val = {60, 100, 120};
   vector < int > wt = \{10, 20, 30\}:
```

```
int capacity = 50;
cout << fractionalKnapsack(val, wt, capacity) << endl;
return 0;</pre>
```

# 2.2 Knapsack 0-1

```
Given n items where each item has some weight and profit
     associated with it and also given a bag with capacity W
     , [i.e., the bag can hold at most W weight in it]. The
    task is to put the items into the bag such that the sum
     of profits associated with them is the maximum
    possible.
Note: The constraint here is we can either put an item
    completely into the bag or cannot put it at all [It is
    not possible to put a part of an item into the bag].
Input: W = 4, profit[] = [1, 2, 3], weight[] = [4, 5, 1]
Output: 3
Explanation: There are two items which have weight less than
     or equal to 4. If we select the item with weight 4,
     the possible profit is 1. And if we select the item
     with weight 1, the possible profit is 3. So the maximum
     possible profit is 3. Note that we cannot put both the
     items with weight 4 and 1 together as the capacity of
     the bag is 4.
Input: W = 3, profit[] = [1, 2, 3], weight[] = [4, 5, 6]
Output: 0
*/
#include <bits/stdc++.h>
using namespace std;
// Function to find the maximum profit
int knapsack(int W, vector<int> &val, vector<int> &wt) {
   // Initializing dp vector
   vector < int > dp(W + 1, 0);
   // Taking first i elements
   for (int i = 1; i <= wt.size(); i++) {</pre>
      // Starting from back, so that we also have data of
       // previous computation of i-1 items
```

# 3 Graph

### 3.7 Floyd-Warshall

```
//Given a matrix dist[][] of size n x n, where dist[i][j]
    represents the weight of the edge from node i to node j
    . If there is no direct edge, dist[i][j] is set to a
    large value (e.g., 10) to represent infinity. The
    diagonal entries dist[i][i] are 0, since the distance
    from a node to itself is zero. The graph may contain
    negative edge weights, but it does not contain any
    negative weight cycles.
//Your task is to determine the shortest path distance
    between all pair of nodes i and j in the graph.
#include <bits/stdc++.h>
using namespace std;
// Solves the all-pairs shortest path
// problem using Floyd Warshall algorithm
void floydWarshall(vector<vector<int>> &dist) {
   int V = dist.size():
   // Add all vertices one by one to
   // the set of intermediate vertices.
   for (int k = 0; k < V; k++) {
      // Pick all vertices as source one by one
       for (int i = 0: i < V: i++) {</pre>
          // Pick all vertices as destination
          // for the above picked source
          for (int i = 0: i < V: i++) {
              // shortest path from
              // i to i
              if(dist[i][k] != 1e8 && dist[k][j]!= 1e8)
```

```
dist[i][i] = min(dist[i][i].dist[i][k] + dist[

#### 3.12 Union-Find

```
1. Find:
The task is to find representative of the set of a given
     element. The representative is always root of the tree.
     So we implement find() by recursively traversing the
     parent array until we hit a node that is root (parent
    of itself).
2. Union:
The task is to combine two sets and make one. It takes two
     elements as input and finds the representatives of
     their sets using the Find operation, and finally puts
    either one of the trees (representing the set) under
     the root node of the other tree.
*/
#include <iostream>
#include <vector>
using namespace std;

    return log2(a) / log2(b);
}
```

### 4.6 Point Inside Triangle

```
// Check if point lies inside a triangle using barycentric
    coordinates
#include <bits/stdc++.h>
using namespace std:
struct point {
   double x, v;
bool is_point_inside_triangle(point A, point B, point C,
    point P) {
   // Calculate the barvcentric coordinates
   // of point P with respect to triangle ABC
   double denominator = ((B.y - C.y) * (A.x - C.x) + (C.x -
        B.x) * (A.v - C.v));
   double a = ((B.y - C.y) * (P.x - C.x) + (C.x - B.x) * (P.x)
        v - C.v)) / denominator:
   double b = ((C.y - A.y) * (P.x - C.x) + (A.x - C.x) * (P.x - C.x)
        y - C.y)) / denominator;
   double c = 1 - a - b:
   // Check if all barvcentric coordinates
   // are non-negative
   return a >= 0 \&\& b >= 0 \&\& c >= 0; // returns true if
        point lies exactly in the border
   // return a > 0 && b > 0 && c 0; returns false if point
        lies exactly in the border
int main() {
   cin.tie(0):
   ios_base::sync_with_stdio(0);
   point A, B, C, P;
   cin >> A.x >> A.y >> B.x >> B.y >> C.x >> C.y;
   cin >> P.x >> P.y;
   cout << (is_point_inside_triangle(A, B, C, P) ? "YES\n" :</pre>
         "NO\n");
   return 0;
```

## 4.7 Primality Test

```
// Optimised school method based C++ program to check if a
// number is prime
- #include <bits/stdc++.h>
```

```
using namespace std;
bool isPrime(int n)
    // Corner case
    if (n <= 1)
       return false;
    // Check from 2 to square root of n
    for (int i = 2; i <= sqrt(n); i++)</pre>
       if (n % i == 0)
           return false:
    return true:
}
// Driver Program to test above function
int main()
    isPrime(11) ? cout << " true\n" : cout << " false\n";</pre>
    isPrime(15) ? cout << " true\n" : cout << " false\n";</pre>
   return 0:
}
// This code is contributed by Vikash Sangai
```

### 4.8 Prime Factorization

```
#include <iostream>
#include <vector>
using namespace std;

int main()
{
   int n;
   cin >> n;
   int spf[n + 1];

for (int i = 2; i <= n; i++)
   spf[i] = i;

for (int x = 2; x <= n; x++) // Calcula o vetor spf
   {
   if (spf[x] != x)
      continue;

   for (int i = 2*x; i <= n; i += x)
   spf[i] = min(spf[i], x);</pre>
```

#### 4.9 Sieve

```
#include <bits/stdc++.h>
using namespace std;
vector<bool> primes;
void sieve(long long n) {
   primes = vector<bool>(n + 1, true);
   primes[0] = primes[1] = false;
   for (int i = 2; i <= sqrt(n); i++) {</pre>
      if (primes[i]) {
          for (int j = i * i; j <= n; j += i) {
              primes[j] = false;
   }
int main() {
   ios_base::sync_with_stdio(false);
   cin.tie(0):
   sieve(100):
   return 0;
```

# 5 String

#### 5.1 Knuth-Morris-Prat

```
Given two strings txt and pat, the task is to return all
    indices of occurrences of pat within txt.
Examples:
Input: txt = abcab . pat = ab
Output: [0, 3]
Explanation: The string ab occurs twice in txt, first
    occurrence starts from index 0 and second from index 3.
Input: txt= aabaacaadaabaaba , pat =
Output: [0, 9, 12]
// C++ program to search the pattern in given text using
// KMP Algorithm
#include <iostream>
#include <string>
#include <vector>
using namespace std;
void constructLps(string &pat, vector<int> &lps) {
   // len stores the length of longest prefix which
   // is also a suffix for the previous index
   int len = 0:
   // lps[0] is always 0
   lps[0] = 0;
   int i = 1:
   while (i < pat.length()) {</pre>
       // If characters match, increment the size of lps
       if (pat[i] == pat[len]) {
          len++:
          lps[i] = len;
          i++:
       // If there is a mismatch
       else {
          if (len != 0) {
```

```
// Update len to the previous lps value
              // to avoid reduntant comparisons
              len = lps[len - 1]:
           }
           else {
              // If no matching prefix found, set lps[i] to
              lps[i] = 0;
              i++:
          }
       }
}
vector<int> search(string &pat, string &txt) {
   int n = txt.length();
   int m = pat.length();
   vector<int> lps(m);
   vector<int> res:
   constructLps(pat, lps);
   // Pointers i and j, for traversing
   // the text and pattern
   int i = 0:
   int j = 0;
   while (i < n) {
       // If characters match, move both pointers forward
       if (txt[i] == pat[i]) {
           i++:
           j++;
           // If the entire pattern is matched
           // store the start index in result
           if (i == m) {
              res.push_back(i - j);
              // Use LPS of previous index to
              // skip unnecessary comparisons
              j = lps[j - 1];
       }
       // If there is a mismatch
       else {
```

### 5.2 Levenshtein's Distance

```
// Calcula o nmero mnimo de operaes necessrias para
    transformar uma string em outra.
//Levenshtein distance is a measure of the similarity
    between two strings, which takes into account the
    number of insertion, deletion and substitution
    operations needed to transform one string into the
// C++ code for the above approach:
#include <bits/stdc++.h>
using namespace std;
int levenshteinTwoMatrixRows(const string& str1,
                         const string& str2)
   int m = str1.length();
   int n = str2.length();
   vector<int> prevRow(n + 1, 0);
   vector<int> currRow(n + 1, 0):
   for (int j = 0; j <= n; j++) {</pre>
       prevRow[j] = j;
```

```
for (int i = 1; i <= m; i++) {</pre>
       currRow[0] = i:
       for (int j = 1; j <= n; j++) {
          if (str1[i - 1] == str2[j - 1]) {
              currRow[j] = prevRow[j - 1];
          }
           else {
              currRow[j] = 1
                         + min(
                             // Insert
                              currRow[j - 1],
                             min(
                                 // Remove
                                 prevRow[j],
                                 // Replace
                                 prevRow[j - 1]));
       prevRow = currRow;
   return currRow[n]:
// Drivers code
int main()
   string str1 = "kitten";
   string str2 = "sitting";
   // Function Call
   int distance = levenshteinTwoMatrixRows(str1, str2);
   cout << "Levenshtein Distance: " << distance;</pre>
   return 0:
```

### 5.3 Longest Common Subsequence

```
/*
Given two strings, s1 and s2, the task is to find the length
of the Longest Common Subsequence. If there is no
common subsequence, return 0. A subsequence is a string
generated from the original string by deleting 0 or
```

```
the remaining characters.
Example:
Input: s1 = AGGTAB , s2 = GXTXAYB
Output: 4
Explanation: The longest common subsequence is GTAB.
// C++ program to find the longest common subsequence of two
     strings
// using space optimization
#include <iostream>
#include <vector>
using namespace std;
int lcs(string &s1, string &s2) {
   int m = s1.length(), n = s2.length();
   // dp vector is initialized to all zeros
   // This vector stores the LCS values for the current row.
   // dp[j] represents LCS of s1[0..i] and s2[0..j]
   vector < int > dp(n + 1, 0);
   // i and j represent the lengths of s1 and s2
        respectively
   for (int i = 1; i <= m; ++i) {</pre>
       // prev stores the value from the previous
       // row and previous column (i-1), (j -1)
       // Used to keep track of LCS[i-1][j-1] while updating
             dp[i]
       int prev = dp[0];
       for (int j = 1; j <= n; ++j) {
          // temp temporarily stores the current
           // dp[j] before it gets updated
           int temp = dp[i]:
          // If characters match, add 1 to the value
          // from the previous row and previous column
           // dp[i] = 1 + LCS[i-1][i-1]
          if (s1[i - 1] == s2[i - 1])
              dp[j] = 1 + prev;
           else
              // Otherwise, take the maximum of the
              // left (dp[j-1]) and top (dp[j]) values
```

more characters, without changing the relative order of

```
dp[j] = max(dp[j - 1], dp[j]);

    // Update prev for the next iteration
    // This keeps the value of the previous
    // row (i-1) for future comparisons
    prev = temp;
}

// The last element of the vector contains the length of
    the LCS
    // dp[n] stores the length of LCS of s1[0..m] and s2[0..n
    ]
    return dp[n];
}

int main() {
    string s1 = "AGGTAB", s2 = "GXTXAYB";
    cout << lcs(s1, s2);
    return 0;
}</pre>
```

### 6 Vector

## 6.1 Binary Search

```
#include <bits/stdc++.h>
using namespace std;
int binarySeach(vector<int> &arr, int val) {
   int l = 0, r = arr.size() - 1;

while (l <= r) {
   int middle = (l + r) / 2;

   if (arr[middle] == val)
      return middle;

   if (arr[middle] < val)
      l = middle + 1;
   else
      r = middle - 1;
}

return -1; // elemento nao encontrado
}</pre>
```

#### 6.2 Kadane

```
#include <bits/stdc++.h>
using namespace std;
int main() {
    ios_base::sync_with_stdio(false);
    cin.tie(0);

    vector<int> arr = {3, -2, 1, 5, -4, 7, 9};

    int MAX = arr[0], sum = arr[0];

    for (int i = 1; i < arr.size(); i++) {
        sum = max(arr[i], sum + arr[i]);
        MAX = max(MAX, sum);
    }

    cout << MAX << '\n';
    return 0;
}</pre>
```

### 6.3 Longest Increasing Subsequence

```
Given an array arr[] of size N, the task is to find the
    length of the Longest Increasing Subsequence (LIS) i.e
    ., the longest possible subsequence in which the
    elements of the subsequence are sorted in increasing
    order, in O(N log N).

Examples:
Input: arr[] = {3, 10, 2, 1, 20}
Output: 3
Explanation: The longest increasing subsequence is 3, 10, 20

Input: arr[] = {3, 2}
Output:1
Explanation: The longest increasing subsequences are {3} and
    {2}

Input: arr[] = {50, 3, 10, 7, 40, 80}
Output: 4
```

```
Explanation: The longest increasing subsequence is {3, 7,
     40, 80}
// Binary Search Approach of Finding LIS by
// reducing the problem to longest
// common Subsequence
#include <bits/stdc++.h>
using namespace std;
int lengthOfLIS(vector<int>& arr)
   // Binary search approach
   int n = arr.size();
   vector<int> ans;
   // Initialize the answer vector with the
   // first element of arr
   ans.push_back(arr[0]);
   for (int i = 1; i < n; i++) {</pre>
       if (arr[i] > ans.back()) {
           // If the current number is greater
           // than the last element of the answer
           // vector, it means we have found a
           // longer increasing subsequence.
           // Hence, we append the current number
           // to the answer vector.
           ans.push_back(arr[i]);
       else {
           // If the current number is not
           // greater than the last element of
           // the answer vector, we perform
           // a binary search to find the smallest
           // element in the answer vector that
           // is greater than or equal to the
           // current number.
           // The lower bound function returns
           // an iterator pointing to the first
           // element that is not less than
           // the current number.
           int low = lower_bound(ans.begin(), ans.end(),
```

```
arr[i])
                   - ans.begin();
          // We update the element at the
          // found position with the current number.
          // By doing this, we are maintaining
          // a sorted order in the answer vector.
          ans[low] = arr[i]:
      }
   }
   // The length of the answer vector
   // represents the length of the
   // longest increasing subsequence.
   return ans.size();
// Driver program to test above function
   vector<int> arr = { 10, 22, 9, 33, 21, 50, 41, 60 };
   // Function call
   printf("Length of LIS is %d\n", lengthOfLIS(arr));
   return 0;
```

# 6.4 Prefix Sum

```
#include <bits/stdc++.h>
using namespace std;
int main() {
    ios_base::sync_with_stdio(false);
    cin.tie(0);

    int n, q;
    cin >> n >> q;

    vector<long long> arr(n + 1);
    arr[0] = 0;
    long long sum = 0, temp;

    for (int i = 1; i <= n; i++) {
        cin >> temp;
        sum += temp;
    }
}
```

```
arr[i] = sum;
}
int a, b;
while (q--) {
   cin >> a >> b;
   cout << arr[b] - arr[a - 1] << '\n';
}
return 0;</pre>
```

### 6.5 Range Xor Queries

```
#include <bits/stdc++.h>
using namespace std;
int main() {
   ios::sync_with_stdio(0);
   cin.tie(0):
   int n, q;
   cin >> n >> q;
   vector<long long> arr(n + 1);
   long long sum = 0, temp;
   for (int i = 1; i <= n; i++) {</pre>
       cin >> temp;
       sum = sum ^ temp:
       arr[i] = sum;
   int a, b;
   while (q--) {
       cin >> a >> b:
       cout << (arr[b] ^ arr[a - 1]) << '\n';</pre>
   return 0;
```
